

Computer Systems Week 1 - Numbers

Lecture Objectives

To introduce the fundamentals of number representations, their conversion and how overflow can create problems in computer programs.

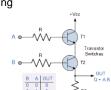

Numbers - Lecture Outline

- ♦ Why do we use binary?
- Representing Text
- ◆ Decimal, Binary, Octal and Hexadecimal Notations
- ◆ How to convert from Decimal to Binary & vice versa?
- Conversion between other notations?
- Overflow and avoiding it
- ◆ Signed Integers 2's complement
- ◆ Illustration of Overflow using Factorial

What are Computers made of?

- A collection of "switches" called transistors.
- Can either be "on" or "off", corresponding to a particular electrical state (conducting or not).
- ◆ Forces "binary" representation
 - ${\color{red}\bullet}\text{``Off''} \rightarrow 0$
 - •"On" → 1
- All data must be represented as sequences of ones and zeros – binary digits – bits
- •As must the computer's "instructions"

Implications?

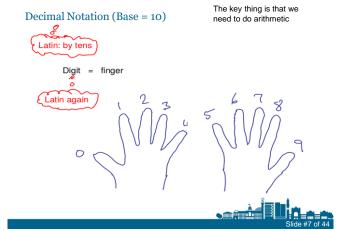

- For practical engineering reasons it is better (cheaper, more reliable, faster ...) to stick with basic components that only have two states – binary.
 - But, in principle, we could build other types of computer and they have been built
- This applies within the processor, memory and all other components
- As an aside, all the data is just a pattern of bits. The interpretation put on it is down to the program:
 - ◆ You can add two character strings or instructions
 - But, there are safeguards in most operating systems and programming languages that restrict this.
- Historically, memory and processing was very limited.
 - It still is, but not to the same extent.

Representing Text

- Every text character is represented as a "binary string"
 A: 1000001
 - B: 1000010
 - C: 1000011
- ◆ Text Encoding Schemes like ASCII, Unicode
 - ♦ These usually use 8, 16 or 32 bits to encode characters
 - Support internationalisation
 https://en.wikipedia.org/wiki/Character_encoding
- Strings (words, names, addresses etc.) are usually represented by a block of characters. See how Java/Python does it.
- Numbers are more <u>subtle</u> 微妙
 Need to worry about arithmetic

Different Notations

System	Base	Symbols	Used by humans?	Used in computers?
Decimal	10	0, 1, 9	Yes	No
Binary	2	0, 1	No	Yes
Octal	8	0, 1, 7	No	No
Hexa- decimal	16	0, 1, 9, A, B, F	No	No

Counting in Different Number Systems (1 of 3)

Decimal	Binary	Octal	Hexa- decimal
0	0	0	0
1	1	1	1
2	10	2	2
3	11	3	3
4	100	4	4
5	101	5	5
6	110	6	6
7	111	7	7

Counting in Different Number Systems (2 of 3)

Decimal	Binary	Octal	Hexa- decimal
8	1000	10	8
9	1001	11	9
10	1010	12	Α
11	1011	13	В
12	1100	14	C
13	1101	15	D
14	1110	16	Е
15	1111	17	F

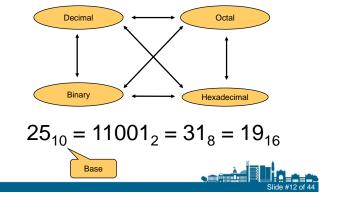

Counting in Different Number Systems (3 of 3)

Decimal	Binary	Octal	Hexa- decimal
16	10000	20	10
17	10001	21	11
18	10010	22	12
19	10011	23	13
20	10100	24	14
21	10101	25	15
22	10110	26	16
23	10111	27	17

Conversion among Different Notations

Conversion - Decimal to Binary

◆ Technique

- ◆ Divide by two, keep track of the remainder
- ◆ First remainder is bit 0 (LSB, Least-Significant Èit)
- ◆ Second remainder is bit 1
- ♦ Etc.

125₁₀ = 1111101₂

Conversion - Binary to Decimal

◆ Technique

- ♦ Multiply each bit by 2^n , where *n* is the "weight" ("positional value") of the bit.
- ◆ The weight is the position of the bit, starting from 0 on the right
- ◆ Add the results

Example

Example

Conversion - Decimal to Octal

- ◆ Technique
 - ◆ Divide by 8
 - ◆ Keep track of the remainder

1234₁₀ = 2322₈

- ◆ Multiply each digit by 8^n , where n is the "weight" of the digit
- ◆ The weight is the position of the digit, starting from 0 on the right
- ◆ Add the results

Conversion - Decimal to Hexadecimal

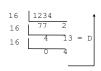

◆ Keep track of the remainder

Example

 $1234_{10} = 4D2_{16}$

 $1234_{10} = ?_{16}$

Conversion - Hexadecimal to Decimal

◆ Technique

- ◆ Multiply each digit by 16 n , where n is the "weight" of the digit
- ◆ The weight is the position of the digit, starting from 0 on the right
- ◆ Add the results

Conversion - Binary to Octal

- ◆ Technique
 - Group bits in threes, starting on right
 - ◆ Convert to octal digits

Example

1011010111₂ = 1327₈

Conversion - Octal to Binary

- ◆ Technique
 - ◆ Convert each octal digit to a 3-bit equivalent binary representation
- ◆ Note: Every digit will be converted to 3 bits, even if all bits are zeros

Example

Conversion - Binary to Hexadecimal

- ◆ Technique
 - ◆ Group bits in fours, starting on right
 - ◆ Convert to hexadecimal digits

Example

 $1010111011_2 = 2BB_{16}$

Conversion - Hexadecimal to Binary

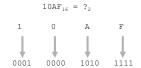

- ◆ Technique
 - ◆ Convert each hexadecimal digit to a 4-bit equivalent binary representation
- ◆ Note: Every digit will be converted to 4 bits, even if all bits are zeros

Example

10AF₁₆ = 0001000010101111₂

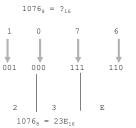

Conversion - Octal to Hexadecimal

- ◆ Technique
 - ♦ Use binary notation as an intermediate representation.

Example

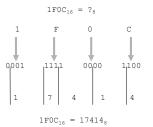

Conversion - Hexadecimal to Octal

- ◆ Technique
 - ◆ Use binary notation as an intermediate representation.

Exercise - Conversions (Home Work)

Decimal	Binary	Octal	Hexa- decimal
33			
	1110101		
		703	
			1AF

Don't use a calculator!

Exercise - Conversions (Answers)

Decimal	Binary	Octal	Hexa- decimal
33	100001	41	21
117	1110101	165	75
451	111000011	703	1C3
431	110101111	657	1AF

Slide #25 of 44

Bits and Numbers (Unsigned)

No of Bits	Min (Binory)	Max (Binary)	Max (Dasimal)
Dito	(Binary)	(Binary)	(Decimal)
1	0	1	1
2	00	11	3
3	000	111	7
4	0000	1111	15
8	00000000	11111111	255
n	00 (n bits)	11 (n bits)	2 ⁿ - 1

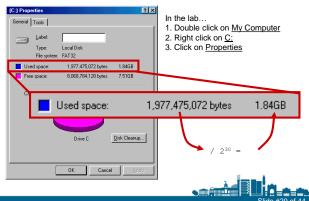

Approximating Big Powers of 2

Binary Value	Value (Exact)	Value (Approx)	Equivalent (Decimal)
2 ¹⁰	1024	1000 (one thousand)	10 ³ (Kilo k)
2 ²⁰	1048576	1000000 (one million)	10 ⁶ (Mega M)
230	1073741824	100000000 (one billion)	10 ⁹ (Giga G)
2 ⁴⁰	1099511628000	100000000000 (one trillion)	10 ¹² (Tera T)

- What is the value of "K", "M", and "G"?
 In computing, particularly w.r.t. <u>memory</u>, the base-2 interpretation generally applies (Column 2)

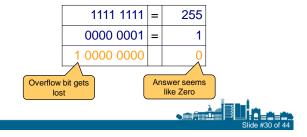

Example - Memory Space

What is Overflow?

- ◆ What is the highest value that can be stored in 8bits? And what happens when arithmetic goes outside the storable range?
- ◆ Example: 255 + 1 in 8 bits ?

What is Overflow?

- ◆ In a given type of computer, the size of integers is a fixed number of bits.
- ◆ 32 or 64 bits are popular choices these days.
- ◆ It is possible that addition of two n bit numbers yields a result requiring n+1 bits.
- Overflow is the term for an operation whose results exceed the space allocated for a number.

Negative Numbers

- ♦ In 8-bit arithmetic 255 + 1 looks like 0, 255 is behaving like -1
- ◆ 11111111 is the two's complement representation of -1
- ◆ More generally, for 2's complement representation (in 8 bits) of a -ve number -X; we can use ordinary binary representation of 256 - X
- ◆ Even more generally, the 2's complement of -X, we can use the following formula: 2n - X
 - Where n is the number of bits

Finding 2's Complement - General Method

◆ Flip all of the bits

Add 1

256 - X	=	255 – X + 1
		(still 8 bits)
255 - X	=	Flip All Bits of X

◆ Example: How to represent -20 in 2's complement?

8-bit Signed Integers

◆ Integers in the range -128 ... +127

Ū	ŭ	
127	0 1111111	
1	00000001	
0	00000000	
-1	1 1111111	
-2	1 11111110	2's complement
-128	10000000	
	s sign: egative (zero or positive) ive numbers	

Range for n-bit Signed Integers

In general for signed integers: -2ⁿ⁻¹ ... 2ⁿ⁻¹-1

• For Example:

	-	
Bits	Minimum	Maximum
8	-128	+127
16	-32768	+32767
32	-2147483648	+2147483647

For un-signed integers: 0 ... 2n-1

Bits	Minimum	Maximum	
8	0	255	
16	0	0 65535	
32	0	4294967295	

Binary Numbers: How they should be treated?

◆ For much of the arithmetic (+, -, *) it does not matter

TRUE

 For comparisons, need to know whether the numbers are signed or unsigned:

For Example:

- signed -1 < 0
- unsigned 255 < 0
 </p> **FALSE**

Integer Numbers - Behavior in Java

- ◆ For integer (whole number) arithmetic:
- •values are treated as signed
- •bits beyond storable range are lost
- •overflow ignored no errors flagged!

Data Types	byte	short	int	long
Bytes	1	2	4	8
Bits	8	16	32	64

A boolean value (true or false) is 1 bit (1 or 0)

Integer Numbers - Sign Extension

- Sometimes you extend a number by giving it more space.
 - •For unsigned arithmetic: just provide extra 0s
- ◆ For signed arithmetic: use sign extension

 •MSB is repeated

 11111111

 11111111
- Java uses sign extension when converting byte to short (and short to int, int to long)

Selecting Appropriate Data Types

Make sure your datatype is big enough for the numbers you want to compute with!

e.g. int for money in pence may be too short

max int =
$$2^{31} - 1$$
 int = 4 bytes = 32 bits unsigned, max = $2^{32} - 1$ but int is signed

≈ 2 x $(2^{10})^3 - 1$ but int is signed

≈ 2 x 10^9 pence $2^{10} = 1024 \approx 10^3$
= £ 2 x $10^7 = £$ 20 million

If amounts go above that, can use long - or BigInteger

How quickly overflow can occur?

```
n factorial (n!) = n * (n-1) * (n-2) * ... * 1
public static void main(String[] args) {
                                                              n, n!
           for (int i = 6; i < 20; i++){
           System.out.println(""+i+", "+fact(i));
                                                               6, 720
                                                               7, 5040
8, 40320
                                                               9, 362880
* Calculate factorial. "requires" comment says
                                                               10, 3628800
11, 39916800
* requires: 0 <= n nothing is guaranteed if n < 0
 @param n number whose factorial is to be calculated
                                                               12, 479001600
* @return factorial of n
                                                               13, 1932053504
                                                                14, 1278945280
public static int fact(int n){
                                                               15, 2004310016
16, 2004189184
                                                               17, -288522240
18. -898433024
           for (int i = 1; i \le n; i++){
                      a = a * i;
                                                               19, 109641728
                            Do you see any problems?
           return a:
```

How quickly overflow can occur?

Obviously wrong for n = 17 or 18 - negative answers 6, 720 Actually, all answers from n = 13 must be wrong n! = n * (n-1) * ... * 10 * ... * 5 * ... * 2 * 17, 5040 8, 40320 9. 362880 10x5x2 = 10010, 3628800 - correct answer must end 00 for n = 10 or more 11, 39916800 12, 479001600 At n = 13 get overflow. After that all the answers are wrong. 14 1278945280 A rough calculation explains why n = 13 is where it 15, 2004310016 goes wrong. 16, 2004189184 17, -288522240 $12! = 479.001.600 \approx 4.79 \times 10^{8}$ 13! = 6,227,020,800 ≈ 6.23 x 10⁹ 18, -898433024 Max int = $2^{31} - 1 = 2,147,483,647 \approx 2.15 \times 10^9$ 19, 109641728 13! is too big for int (signed 32-bit integer)

A Slightly Better Version!

```
public static void main(String[] args) {
            for (int i = 6; i < 20; i++){
            System.out.println(""+i+", "+fact(i));
* Calculate factorial.
* requires: 0 <= n <= 12
 @param n number whose factorial is to be calculated
* @return factorial of n
                                                                Alternatively:
public static int fact(int n){
            int a = 1;
                                                                Use long (but still overflow)
            for (int i = 1; i \le n; i++){
                                                                Use BigInteger
                        a = a * i;
                                                                (or Python)
            return a;
```

Long Version!

```
/**

* Calculate factorial.

* requires: 0 <= n <= 20

* @param n number whose factorial is to be calculated

* @return factorial of n

*/
public static long lfact(int n){
    long a = 1;
    for (int i = 1; i <= n; i++){
        a = a * i;
    }
    return a;
}

Works up to n = 20

* n, n!

6, 720
7, 5040
8, 40320
9, 362880

```

Summary

Representing numbers in the computer

- Whole numbers in binary, octal, decimal and hexadecimal notations
- Converting from one representation to another
- Representing negative numbers
- Overflow and its consequences.
